Introduction

Visual impairment is a global health problem. Cataract is responsible for 50% of blindness worldwide [1].

Posterior capsular opacification is the most common late complication of cataract surgery as a result of proliferation of residual lens epithelial cells overall 25% of patients undergoing extracapsular cataract surgery develops visually significant PCO within 5 years of the operation [2].

Nd: YAG laser provides the advantage of cutting the posterior lens capsule, thereby avoiding and minimizing infection, wound leaks, and other complication of intraocular surgery. Thus Nd:YAG laser capsulotomy is noninvasive, effective and relatively safe technique [3].

However, this procedure is associated with complications such as post-operative increased intraocular pressure (IOP), cystoid macular edema (CME), disruption of the anterior vitreous surface, uveitis, lens subluxation, increased incidence of retinal detachment and pitting of the IOL [4].

Laser shots can be applied in several patterns such as “Cruciate or Cross pattern”, “Can opener”, inverted “U-Method” and in a “Circular pattern”. Many authors promote the use of a cruciate pattern in the Centre of the visual axis, with the clinician starting off on both axes away from the Centre to avoid pitting the lens centrally [5].

This study mainly aims to analyze the effect of various forms of PCO capsulotomy openings on visual function after Nd: YAG capsulotomy.

Materials and methods

Source of data

The materials for the present study drawn from patients attending the outpatient department of ophthalmology. After considering the below criteria, patients were selected into the study.

Inclusion criteria

All patients presented with diminution of vision due to posterior capsular opacity,

5. Aphakic eyes.

Methodology

Study was initiated after obtaining approval from the Institutional Ethics Committee. Study conducted in about 100 PCO patients fulfilling the inclusion criteria after obtaining the informed consent from the participants are subjected to:

- A detailed clinical history includes date of cataract surgery, interval between cataract surgery and onset of defective vision, history of glaucoma, history of any systemic illnesses or surgery, history of any other ocular conditions.
- Detailed examination of both eyes along with general physical examination.
- Visual acuity testing with Snellen’s chart.
- Examination of anterior segment of eye by slit lamp biomicroscopy.
- Measurement of intraocular pressure using applanation tonometer (Perkins).

Examination of posterior segment of eye by ophthalmoscopy (direct and indirect) and +90 D biomicroscopy.

A Q-switched Nd: YAG laser system (YAG IIplus, Appa swamy, India), with wavelength of 1064 nm and pulse length of < 4 ns (2-3 ns) was employed for this study. Before starting the procedure, one drop of 4% xylocaine was instilled into the conjunctival cul-de-sac.

The pupils were fully dilated and the aim was to create a capsulotomy of about 4 mm in size.

In cruciate pattern posterior capsulotomy laser shot is first aimed superiorly at near 12 Clock in the location of fine tension lines and progressing downwards towards the 6 o’clock position, shots are then placed at the edge of the capsule opening, progressing laterally towards the 3 and 9 o’clock positions. In circular pattern a circle of laser shots put starting from 6 o’clock position with a diameter of 4-5 mm.

The aiming beam was focused slightly posterior to the posterior capsule. The optical center of the IOL was matched with the center of the opening. Initial setting of 1mJ and subsequent increase of 0.5 mJ as necessary used to make an opening in the posterior capsule.

Post procedure Tab Acetazolamide 250mg BD, Moxifloxacin with Dexamethasone eye drops QID, Nepafenac eye drops BD depending on the inflammatory response and raised IOP. Antiglaucoma medications were not given prior to capsulotomy to any patient.

Follow up

Patients were visited on first, third and seventh postoperative days, then weekly for two weeks, monthly for two months and on third month. Each visit patients visual acuity, refraction, fundoscopy and IOP were examined and analysed. More frequent follow up visits may be considered in patients with complications.

Results and observations

After a study for 18 months Dec 2017- May 2019 the following observations were made, 100 patients were identified having posterior capsular opacity, These patients were divided into group A and group B, group A underwent cruciate and group B underwent circular pattern capsulotomy (Table 1).

Graph 1 showing both circular and cruciate pattern capsulotomy have almost same outcome.
In cases who underwent circular pattern complications like IOL pitting and uveits are common compared cruciate pattern, where IOP spikes is a common complication (Table 2).

There was a single case of CME found in circular pattern and single case of ant hyaloid face rupture found in patients undergone cruciate pattern of capsulotomy.

Graph 2 showing complication rate is more with the cruciate pattern capsulotomy compared to circular pattern.

24.5% of cases under gone circular pattern of capsulotomy were complaining of floaters compared to cruciate only 10% (Table 3).

This is not statistically significant but cruciate pattern have less chances of floaters compared to circular.

Graph 3 showing circular pattern have higher chances of having floaters compared to cruciate pattern capsulotomy.

Discussion

The circular pattern laser shots avoid the visual axis which resulted in decreased frequency of IOL Pitting which can cause glare and light scattering and be visually disabling. Thus, the circular technique can prevent any damage near the visual axis of IOL and generate sufficiently large size of the capsulotomy to restore contrast sensitivity and overcome glare disability. In patients who underwent circular pattern capsulotomy there was an immediate improvement of VA compared to these who underwent conventional cruciate method.

Mahmood Soni Wali et al study done on 58 patients were divided into two groups. In one group cruciate pattern of laser shots were given and in the 2nd group circular pattern of laser shots was used. Immediate visual outcome on 1st day was better with circular pattern. The incidence of IOP spike was less with circular pattern as compared to cruciate pattern. The IOL Lens pitting, CME and retinal detachment were not observed in patients who underwent circular pattern laser capsulotomies [6].

In our study in cases who underwent circular pattern complications like IOL pitting (83.3%), uveitis (75%) and CME (100%) are common compared cruciate pattern IOP spikes (55%) and Hyaloid face rupture (100%) is common in cruciate pattern compared to circular pattern.

Conclusion

The cruciate pattern Nd: YAG posterior laser capsulotomy can be performed safely but visual prognosis is better in circular pattern of capsulotomy. Complications like IOL pitting, uveitis and CME are common in cases who underwent circular pattern compared to cruciate pattern IOP spikes and Hyaloid face rupture is common in cruciate pattern.
